Customer Enablement Automation Roadmap: 2026

1. Enablement Designer Agent (EDA) Experience

Persona

Functional Consultant / Solution Architect / Customer Enablement Lead

Goal

Shrink time from customer requirements to a validated configuration plan, reduce onboarding defects, and standardize fit-gap decisions with traceable evidence.

EDA scope (consolidated capabilities)

- Requirements intake & normalization: convert unstructured inputs into a Customer Requirement Spec (CRS); flag ambiguities and missing fields.
- Evidence retrieval: pull the most relevant functional documentation, FSD references, user stories, and release notes with versioned pointers.
- Capability mapping: map each requirement to the right lane (A: configure in product, B: integrate/orchestrate via IO/Canvas, C: gap requiring build, D: not supported / redesign).
- Fit-gap assessment: produce a requirement-by-requirement decision matrix (risks, assumptions, decisions, and required sign-offs).
- Configuration playbook: generate step-by-step configuration guidance with validation checkpoints and rollback notes.

Experience 1: “Customer requirements → fit-gap assessment → step-by-step configuration playbook”

Trigger

- New customer onboarding or expansion (new product/capability, new segment, new region).
- Change request impacting pricing, eligibility, propositions, or integration behavior.

Step-by-step flow (what the user experiences)

Step 1 - Upload / connect the requirement package

User provides: onboarding requirement doc, epics/user stories, sample products, sample customer/account data, and (if applicable) on-prem artifacts (config exports, rules, mapping docs).

Step 2 - EDA normalizes inputs into a Customer Requirement Spec (CRS)

System produces a structured CRS with: scope, pricing constructs, eligibility rules, exceptions, data dependencies, and non-functional constraints. It highlights missing fields and requests clarifications.

Step 3 - EDA retrieves evidence and anchors recommendations

System assembles supporting documentation snippets and versioned references (Zafin Docs, FSDs, release notes, and known patterns). Every recommendation is linked back to evidence.

Step 4 - EDA maps requirements to capability lanes

Classifies each requirement into lanes: A) configurable in product, B) integrate/orchestrate via IO/Canvas, C) gap requiring build, D) not supported / redesign needed. Adds confidence and rationale.

Step 5 - EDA produces a traceable fit-gap assessment

Outputs a requirement-by-requirement matrix with: fit status, recommended approach, impacted modules, required data, risks, and open questions. Flags design decisions that require customer sign-off.

Step 6 - EDA generates the configuration playbook

Creates a phased, step-by-step guide: prerequisites, object creation order, naming conventions, validation points, and rollback options. Produces a checklist the enablement team can execute consistently.

Step 7 - EDA publishes the Enablement Package for handoff

A single handoff artifact containing CRS, fit-gap report, configuration playbook, and traceability (requirement-to-decision). Items marked for IO/Canvas or build are forwarded to the Integration & Build Guidance Agent; test intent is forwarded to the QA & Regression Agent.

Primary outputs

- Fit-gap assessment (decision matrix + risks + decision points).
- Configuration playbook aligned to lanes A/B/C/D (configurable in product vs IO/Canvas vs gap build vs not supported).
- Interface Mapping Document by identifying the required data (for example: customer segment, balance, transaction code etc) and mapping them to the interfaces/APIs.
- Role Based Access Control mapping document that be used for misite configurations.
- High Level Functional Scenarios with the expected system behavior. This can be used to build test cases.
- Consolidated list of clarification questions that can be asked to the client.

- RACI Matrix

Enablement KPI targets

- Time-to-first fit-gap draft: days → 24 hours for standard use cases (target).
- Defect leakage: reduce onboarding/UAT defects by 30-50% for recurring patterns (target).
- Traceability: 100% of requirements mapped to a decision + linked evidence (target).
- Consistency: fewer knowledge-dependency escalations and rework cycles; repeatable playbooks.
- Accuracy Rate of the Produced Output. >80%
- Adoption Rate by employees >95%
- productivity Gain: Agent vs without agent.

Experience 2: "Enablement engineer exploring a use case → instant guided configuration outline"

Trigger

Any enablement engineer selects a module + use case (or past customer pattern) and asks: "How do we configure this?"

What the guided view provides (opinionated and checklist-driven)

- Configuration outline (objects, order, dependencies).
- Typical clarifying questions to ask the customer (to avoid late surprises).
- Known pitfalls and common gaps (and when IO/Canvas is the right path).
- Starter qualification test intent pack for the use case (scenarios + required data).

Experience 3: "On-prem artifacts → coverage mapping → modernization fit-gap and backlog guidance"

Trigger

- Customer moving from on-prem deployment to the current product + integration stack.
- Customer wants to retain bespoke pricing logic and custom outputs during migration.

Step-by-step flow

Step 1 - Ingest on-prem artifacts

Import configuration exports, mapping documents, custom rule descriptions, and sample calculations/outcomes.

Step 2 - Extract behavior (what the on-prem system actually does)

Create a normalized list of behaviors: inputs, conditions, outputs, exceptions, and dependencies.

Step 3 - Map coverage against current capabilities

Produce a side-by-side mapping: on-prem behavior → current product feature/config path → recommended lane (A/B/C/D).

Step 4 - Create build-ready backlog guidance for gaps

For gaps, propose: IO/Canvas integration approach, product enhancement candidate, or redesign recommendation. Generate story-ready acceptance criteria and test intent.

Step 5 - Publish modernization plan

Phase the transition: quick wins, parity path, and platform-advantage opportunities (standardization, simplified operations, governance).

Outputs

- Coverage matrix: covered as-is, covered with configuration change, gap - build, gap - redesign.
- Modernization plan with sequencing and decision points.
- Gap backlog guidance with acceptance criteria and test intent (handoff-ready).

2. Integration & Build Guidance Agent Experience (IO / Canvas)

Persona

Integration Engineer / Platform Engineer

Goal

When a requirement is not satisfied by product configuration alone, accelerate IO/Canvas build work with a safe, testable, and supportable blueprint.

Experience: “Gap identified → IO/Canvas build spec → contract tests → deployable package”

Trigger

EDA fit-gap output includes items labeled “needs IO/Canvas” or “gap requiring build”.

Step-by-step flow

Step 1 - Generate an engineering build spec (Cursor-ready)

Includes: data contracts, transformations, orchestration logic, error handling, idempotency expectations, monitoring, and audit requirements.

Step 2 - Generate contract tests

Creates request/response samples, golden datasets, negative cases, and schema validation tests to enforce predictable integration behavior.

Step 3 - Produce implementation checklist and CI hooks

Defines how to run tests locally and in CI, and how to validate in a dedicated non-prod environment. Produces a definition of done aligned to enablement and support needs.

Step 4 - Produce an evidence bundle for enablement sign-off

Summarizes what was built, how it was tested, and what operational guardrails exist (alerts, dashboards, runbooks).

Outputs / Engineering KPI targets

- Build cycle time: reduce time-to-first working integration by 25-40% (target).
- Integration reliability: fewer late-stage payload surprises via contract tests.
- Operational readiness: monitoring + runbook requirements embedded in the spec.

3. Quality Assurance & Regression Agent Experience

Persona

QA Lead / Test Automation Lead

Goal

Ensure customer-specific configurations and integrations are qualified against requirements, and remain stable across releases (regression safety net).

Experience 1: "Customer qualification pack → automated execution → evidence-driven sign-off"

Trigger

Configuration playbook is completed (or in-progress) in a test environment; IO/Canvas items are available for validation.

Step-by-step flow

Step 1 - Generate and run customer qualification scenarios and sample data

Generate customer-specific scenarios (try edge cases) and sample data derived from CRS and traceability (happy path, boundary, negative, exception). Create test cases, execute calculations, eligibility, exceptions, outputs, and audit expectations, and validate results against expected outcomes.

Step 2 - Capture evidence automatically

Capture inputs, outputs, rule decisions, and traceability links per test. Produce a pass/fail report with the reason and the exact requirement impacted.

Step 3 - Automate defect creation

Failures create work items with reproduction steps, expected vs actual, and attached evidence.

Experience 2: “Release candidate → regression run → risk report for enablement”

Trigger

A new product release / patch is available for validation.

Step-by-step flow

Step 1 - Run module baseline regression packs

Run standard regression packs per module and common implementation patterns (including known customer hot-spots).

Step 2 - Publish risk and change-impact report

Highlight behavior changes, impacted test clusters, and recommended enablement actions (re-qualify specific customer packs, update playbooks, or block promotion).

Outputs / Quality KPI targets

- Qualification completeness: every requirement has at least one test scenario (target).
- Regression coverage: increase release confidence and reduce hotfix-driven onboarding delays.
- Evidence-driven approvals: standardized sign-off package for customer readiness.

4. Agent Roles and Responsibilities

Core agents (focused set)

- Enablement Designer Agent (EDA): owns CRS, evidence-backed fit-gap, and configuration playbook outputs; produces the Enablement Package handoff.
- Integration & Build Guidance Agent: owns IO/Canvas build specs, contracts, and operational readiness artifacts for gaps requiring integration/build.
- Quality Assurance & Regression Agent: owns customer qualification packs, automated execution evidence, and release regression + risk reporting.

Phase 2+ capability (kept intentionally gated)

- Non-Prod Configuration & Test Execution Automation (Phase 2+): applies controlled configuration changes in non-prod via supported APIs/imports, executes qualification tests, and enforces approvals + rollback. This is introduced only after regression stability and governance are proven.

5. Tooling Integration Map

Systems of record (inputs)

- Customer requirements repository: onboarding docs, epics/user stories, acceptance criteria.
- Product knowledge sources: Zafin Docs, functional specs (FSD), release notes, known implementation patterns.
- Work tracking: Jira (for gaps, decisions, and execution tasks).
- Source control + CI pipelines: GitHub (for IO/Canvas builds and automated test execution).

Evidence and execution surfaces

- Enablement Package workspace: single link containing CRS, fit-gap, playbook, test intent/coverage, and build specs.
- Test results store: pass/fail, diffs, artifacts, and traceability.
- Operational readiness artifacts: dashboards, runbooks, monitoring rules for any integration/build items.

Integration priorities (recommended order)

- Start with read-only connectors first (docs + release notes + existing story patterns) to generate CRS and fit-gap safely.
- Add work-tracking integration next (create/update backlog items with traceability links).
- Then add test execution integration (CI runner + artifact store) so qualification and regression become push-button.
- Only after those are stable, introduce direct configuration automation in non-prod with approvals and rollback.

6. Deliverables

Deliverable 1 - Enablement Designer foundation (Phase 1)

- CRS schema + intake experience for onboarding teams.
- Evidence-linked capability mapping and lane classification.
- Generated configuration playbook with prerequisites and validation checkpoints.
- Fit-gap assessment output packaged as a single handoff artifact.

Deliverable 2 - Integration & build acceleration (Phase 3)

- Cursor-ready IO/Canvas build specs with operational guardrails.
- Contract test generation (schemas, golden datasets, negative cases).
- CI hooks and definition-of-done checklist.

Deliverable 3 - Customer qualification + regression automation (Phase 2 and Phase 4)

- Customer qualification pack generator (scenario + data + expected outcomes).
- Regression suite baseline per module and common patterns.

- Evidence bundles for sign-off and release impact reporting.

Deliverable 4 - Controlled direct configuration in non-prod (Phase 5)

- Non-prod configuration execution with guardrails and rollback.
- Promotion gating based on test evidence and approvals.
- Change log and audit trail per customer and per environment.

7. Guardrails - non-negotiable

- Security and customer isolation: strict tenant scoping, redaction of secrets/PII in artifacts, and role-based access by function.
- Determinism: recommendations must be reproducible; versioned knowledge sources and clear assumptions per output.
- Human-in-the-loop by default: agents recommend; humans approve and execute until Phase 2+ execution is proven safe.
- Explainability: every mapping decision includes why and evidence references.
- Change control: immutable audit trail of generated artifacts, approvals, and executed actions.
- Graceful degradation: if a subsystem fails (retrieval, tests, execution), outputs fall back safely (no silent partial config).

8. MVP Phasing

- Phase 1 - Guided enablement foundation (EDA): CRS intake, evidence retrieval, fit-gap, and configuration playbook generation.
- Phase 2 - Customer qualification automation (QA): auto-generated qualification scenarios + evidence bundles for sign-off.
- Phase 3 - IO/Canvas build guidance (Integration): build specs, contracts, and CI-connected contract tests.
- Phase 4 - Release regression safety net (QA): module regression baselines + release impact/risk reporting.
- Phase 5 - Direct configuration and test execution in non-prod (Phase 2+ capability): gated execution, rollback plans, and promotion checks; expand coverage over time.
